

- The algorithms that I used to match was the rapidfuzz which by default uses edit distance. I maintained a threshold of 85 to check.
- Some problems that I had was that because I left the ratings for the movie in the title i had to strip that from the title to get accurate results, I Also had issues due to the fact that several movies had sequels that had extremely similar titles. Because of this I added a little user input if the title was not exactly the same, so that i could have the final say of what gets added. There were also some issues when i tried comparing the MPA ratings as well as the year, this is because sometimes the year will be off by one and the rating will be comparing the TV rating to a theater rating so it wasn't always the same, there for i relied heavily on if the titles matched.
- Tuple counts
 - Table A = 1000 tuples
 - Table B = 1008 tuples
 - A x B = 100800 tuples
 - Table C = 152 tuples
- I didn't do any cleaning, however when extracting the title I striped the rating. And when extracting the year from table B I removed the month and the day from the date so that I could accurately compare the years.
